

EXAMINER'S AMENDMENT CLAIMS

IN THE CLAIMS:

Listing of Claims:

1. **(Currently Amended)** An apparatus for processing an image signal which converts a first image signal constituted of plural items of pixel data into a second image signal constituted of plural items of pixel data, said apparatus comprising:

a plurality of frame memory portions for storing pixel data of a plurality of consecutive frames of the first image signal together with a motion vector that corresponds to the pixel data and lies between mutually adjacent frames;

data selection means for selecting plural items of pixel data located respectively in a time directional periphery and a space directional periphery with respect to a target position in the second image signal based on the plurality of frames stored in the plurality of frame memory portions; and

pixel data generation means for generating pixel data of the target position in the second image signal by using the plural items of pixel data selected by the data selection means,

wherein each of the frame memory portions has a plurality of banks,

wherein the frames are divided into units of major blocks in which a plurality of minor blocks are arranged two-dimensionally, the minor blocks located at different positions in the major blocks are stored in each of the plurality of banks,

wherein the data selection means selects:

plural items of pixel data located in the space directional periphery with respect to the target position from the frame memory portion in which a current frame in the first

image signal is stored, said current frame corresponding to a frame in which the target position in the second image signal is present; and

plural items of pixel data located in the space directional periphery with respect to a position obtained by performing motion compensation on the target position by using the motion vector stored in the plurality of frame memory portions together with the pixel data, from the frame memory portions in which frames before and after the current frame are stored.

2. **(Original)** The apparatus for processing an image signal according to claim 1, wherein the pixel data generation means comprises:

class detection means for detecting a class to which the pixel data of the target position in the second image signal belongs;

coefficient data generation means for generating coefficient data for an estimation equation that corresponds to the class detected by the class detection means; and

calculation means for obtaining, by calculations, the pixel data of the target position in the second image signal based on the estimation equation by using the coefficient data generated by the coefficient data generation means and the plural items of pixel data selected by the data selection means.

3. **(Original)** The apparatus for processing an image signal according to claim 2, wherein the class detection means detects the class to which the pixel data of the target position in the second image signal belongs, by using at least the plural items of pixel data selected by the data selection means.

4. **Canceled**

5. **(Currently Amended)** A method for an image signal processing apparatus for processing an image signal which converts a first image signal constituted of plural items of pixel data into a second image signal constituted of plural items of pixel data, said method comprising:

a first step of storing pixel data of a plurality of consecutive frames of the first image signal in a plurality of frame memory portions together with a motion vector that corresponds to the pixel data and lies between mutually adjacent frames;

a second step of selecting plural items of pixel data located respectively in a time directional periphery and a space directional periphery with respect to a target position in the second image signal based on the plurality of frames stored in the plurality of frame memory portions; and

a third step of generating pixel data of the target position in the second image signal by using the plural items of pixel data selected by the second step,

wherein each of the frame memory portions has a plurality of banks,

wherein the frames are divided into units of major blocks in which a plurality of minor blocks are arranged two-dimensionally, the minor blocks located at different positions in the major blocks are stored in each of the plurality of banks,

wherein in the second step,

plural items of pixel data located in the space directional periphery with respect to the target position are selected from the frame memory portion in which a current frame in the

first image signal is stored, said current frame corresponding to a frame in which the target position in the second image signal is present; and

plural items of pixel data located in the space directional periphery with respect to a position obtained by performing motion compensation on the target position by using the motion vector stored in the plurality of frame memory portions together with the pixel data, are selected from the frame memory portions in which frames before and after the current frame are stored.

6. **(Currently Amended)** A computer-readable medium recording a program that causes a computer to perform a method for processing an image signal, in order to convert a first image signal constituted of plural items of pixel data into a second image signal constituted of plural items of pixel data, said method comprising:

a first step of storing pixel data of a plurality of consecutive frames of the first image signal in a plurality of frame memory portions together with a motion vector that corresponds to the pixel data and lies between mutually adjacent frames;

a second step of selecting plural items of pixel data located respectively in a time directional periphery and a space directional periphery with respect to a target position in the second image signal based on the plurality of frames stored in the plurality of frame memory portions; and

a third step of generating pixel data of the target position in the second image signal by using the plural items of pixel data selected by the second step,

wherein each of the frame memory portions has a plurality of banks.

wherein the frames are divided into units of major blocks in which a plurality of minor blocks are arranged two-dimensionally, the minor blocks located at different positions in the major blocks are stored in each of the plurality of banks.

wherein in the second step,

plural items of pixel data located in the space directional periphery with respect to the target position are selected from the frame memory portion in which a current frame in the first image signal is stored, said current frame corresponding to a frame in which the target position in the second image signal is present; and

plural items of pixel data located in the space directional periphery with respect to a position obtained by performing motion compensation on the target position by using the motion vector stored in the plurality of frame memory portions together with the pixel data, are selected from the frame memory portions in which frames before and after the current frame are stored.

7. **(Currently Amended)** A program, stored on a computer-readable medium, that causes a computer to perform a method for processing an image signal, in order to convert a first image signal constituted of plural items of pixel data into a second image signal constituted of plural items of pixel data, said method comprising:

 a first step of storing pixel data of a plurality of consecutive frames of the first image signal in a plurality of frame memory portions together with a motion vector that corresponds to the pixel data and lies between mutually adjacent frames;

 a second step of selecting plural items of pixel data located respectively in a time directional periphery and a space directional periphery with respect to a target position in the

second image signal based on the plurality of frames stored in the plurality of frame memory portions; and

a third step of generating pixel data of the target position in the second image signal by using the plural items of pixel data selected by the second step,

wherein each of the frame memory portions has a plurality of banks,

wherein the frames are divided into units of major blocks in which a plurality of minor blocks are arranged two-dimensionally, the minor blocks located at different positions in the major blocks are stored in each of the plurality of banks,

wherein in the second step,

plural items of pixel data located in the space directional periphery with respect to the target position are selected from the frame memory portion in which a current frame in the first image signal is stored, said current frame corresponding to a frame in which the target position in the second image signal is present; and

plural items of pixel data located in the space directional periphery with respect to a position obtained by performing motion compensation on the target position by using the motion vector stored in the plurality of frame memory portions together with the pixel data, are selected from the frame memory portions in which frames before and after the current frame are stored.
